University of Tennessee

**Introduction**  
 This poster discusses CTD as a rapidly progressive and fatal neurodegenerative disease caused by misfolding of the normal protein (PrP<sup>Sc</sup>) into a pathological conformation (PrP<sup>Sc</sup>).

World Health Organization diagnostic criteria for sporadic CTD include: rapidly progressive dementia and at least two of the following: myoclonus, visual or cerebellar signs, peripheral neuropathic signs, or autonomic features. Autopsy must be at least one of the following laboratory tests: amyloid, spongiform degeneration (SD), or a positive 14-3-3 gamma immunoblot assay, and without positive immunohistochemistry indicating an alternative diagnosis.

Although CTD 14-3-3 assay is an important diagnostic criteria, it is neither highly sensitive nor specific and should be repeated three times to increase its diagnostic value. This could potentially delay time to diagnosis.

**THE PRESENT**  
 We will use electron microscopy
